

AI Poker

POKER APPLIKATION

Welcome to AI poker,
a game created for
mobile phones

AI Poker

Introduction

Poker is a type of card game, using a standard 52-card deck, in which players bet on the value of the card combination ("hand") in their possession, by placing a bet into a central pot. The winner of the pot is the non-folded player who holds the hand with the highest value according to an established hand rankings hierarchy (rare card combinations are more valuable than common).

AI Poker is a poker game where the players are autonomous Java programs run from mobile phones. The variant of poker used by AI Poker is called five-card draw¹. *Note that this is not the same as Texas Hold 'Em, the currently most popular poker variant.*

Requirements

AI Poker requires that a minimum of three AI Poker MIDlets² are run simultaneously; one server and two clients. The server controls the whole game while the clients participate in the game, playing against each other. A maximum of five clients (players) can be connected to the server at the same time, playing against each other. This is explained in more detail in the chapter "Playing AI Poker".

Playing the game

In simple terms, AI Poker works like this: The server application allows clients to connect to it, and once all clients are connected the game starts. The game is controlled by the server. When a player needs to make a decision, the server sends a query to the player.

Once started, the game goes in a loop until only a single player remains (has chips left). The loop, controlled by the server, performs these actions each playing round:

1. The server informs all the players how many chips each player has.
2. The players receive five cards each from the server.
3. A forced bet (ante) is drawn from each player and put into the pot.
4. The first betting round.³
5. The draw phase, in which each player is offered to discard some of the cards on hand and receive new cards as replacement for the discarded. The player chooses the what cards to discard (if any).
6. The second betting round.
7. The showdown, which determines the winner of the round. The winner receives the contents of the pot. (In case of multiple winners, the pot is split.)

Each betting round starts with a player making an opening action: "*check*", which is to not place a bet (the opportunity to open moves to the next player); "*open*", which is to make the first bet; or going "*all-in*", which is to open with all the players remaining chips. Once the round has been opened each player may "*fold*", which is to drop out of the hand losing any bets they have already made (but not risking any more); "*call*", which is to match the highest bet so far made; "*raise*", which is to increase the previous high bet; or go "*all-in*", which is to put all the players remaining chips in the pot.

Welcome to AI Poker!

¹ See e.g. http://en.wikipedia.org/wiki/Five-card_draw.

² A Java program for mobile phones are called a MIDlet.

³ For information about betting in poker, see e.g. [http://en.wikipedia.org/wiki/Betting_\(poker\)](http://en.wikipedia.org/wiki/Betting_(poker)).

Programming

Programming in Java for mobile phones

Java by itself is platform independent and there is no difference in the language between different platforms. However, there are still notable differences between developing in Java for desktop applications and developing in Java for mobile phones. Here is a short list of major differences:

- Java for mobile phones is called Java ME⁴, just like java for desktop applications are called Java SE⁵. Java ME programs are called *MIDlets*, just like Java programs for (desktop) web browsers are called applets.
- Java ME for mobile phones consists of a configuration (CLDC), a profile (MIDP) and optional extension packages⁶. Especially the support for extension packages differ between different phones, making the platform more diverse than the PC platform.
- The API for Java ME is *much* smaller than the API for Java SE.
- Generics are not supported.
- Making the user interface look exactly the same on all platforms are not easy:
 - If the standard GUI components are used, they differ between different mobile phones (especially between different brands) and between mobile phones and mobile phone emulators. Developing a GUI in NetBeans becomes less of WYSIWYG⁷ and more of WYSISYI⁸.
 - If the user interface is drawn manually, different screen sizes, different key pads and different colors make it difficult to adapt to different mobile phones.
- Internet access is very much possible, but needs to be run from a thread not handling the applications GUI or the application will dead-lock when the phone asks the user if internet access should be allowed, interrupting the application GUI to do so.

Getting started with the programming

Downloading NetBeans

NetBeans 6.1 with Mobility Pack: <http://download.netbeans.org/netbeans/6.1/final/>.

Downloading additional emulators

While NetBeans 6.1 with Mobility Pack includes a mobile phone emulator developed by Sun that can be used to test AI Poker algorithms on the desktop, the Sun emulator is not as accurate as the emulators provided by the major mobile phone companies, including Sony Ericsson and Nokia. If such emulators are downloaded, NetBeans can be set up to use them instead of the Sun emulator.

Documentation

After installation of NetBeans 6.1 with Mobility Pack, the API documentation for CLDC 1.1 and MIDP 2.0 can be found in *C:\Program Files\NetBeans 6.1\mobility8\WTK2.5.2\docs\api\midp\index.html* on a typical Windows computer.

⁴ Short for Java Platform, Micro Edition. See http://en.wikipedia.org/wiki/Java_Platform,_Micro_Edition.

⁵ Short for Java Platform, Standard Edition.

⁶ Examples of what is optional: Java support for Bluetooth, file access and 3D graphics, to name a few.

⁷ What You See Is What You Get.

⁸ What You See Is What You Intended.

Opening the project

The AI Poker project is opened like any other project in NetBeans, by locating the folder. However, the project has some external dependencies that NetBeans might need help to find. The external dependencies are located in the “External” folder relative the project folder.

Embedding AI functionality

The class *PokerClient* should be modified. Strictly speaking, most of the *info**-methods are only to inform what actions other players (or you!) do so if the information is not needed, changing the method can be skipped, but the *query**-methods are required to be changed or the program will fail.

The methods in the *PokerClient* class are called from the abstract base class *PokerClientBase*. It is the base class that interprets messages sent from the poker server.

Compiling and running the project

The program are compiled like any other NetBeans project and when run, a mobile phone emulator will start and allow you to test the MIDlet on your desktop computer. The emulator also allows you to debug your application.

The compilation will generate two files and put them into the projects *dist*-folder: *PokerApplication.jar* and *PokerApplication.jad*. The JAD file is a text file that describes the content of the jar file. You typically need only the JAR file to install the program on a mobile phone.

Installing the AI Poker MIDlet on a mobile phone

The exact installation procedure differs between different mobile phones, but three common, mutually exclusive, ways to install the program are:

- Connecting the mobile phone to the computer using an USB cable and using PC software from the mobile phone manufacturer to install the MIDlet on the phone.
- Connecting the mobile phone to the computer using an USB cable, transferring the JAR file from the computer to the mobile phone and then using the mobiles file browser to open and install the JAR file.
- Uploading the JAR file from the desktop to a web server, thereafter using the mobile phones web browser to enter the web address of the JAR file and download and install the program.

Installing the AI Poker MIDlet on Sony Ericsson G900

While the above alternatives work also for the Sony Ericsson G900, here are more detailed instructions:

Option 1: Installing using Sony Ericsson PC Suite

The first and recommended option is to:

1. Go to <http://www.sonyericsson.com/cws/support/softwaredownloads/g900?cc=se&lc=sv> (Swedish) or <http://www.sonyericsson.com/cws/support/softwaredownloads/g900> (international).
2. Download the PC Suite for Sony Ericsson G900.

Sony Ericsson - Support - G900 - Software - Windows Internet Explorer

Håll ordning och reda

PC Suite
Med PC Suite för Sony Ericsson kan du ansluta telefonen till datorn så att du kan synkronisera och hantera personliga uppgifter (till exempel kalender och kontaktinformation) och ansluta datorn till Internet via telefonen.
[Läs mer och ladda ner](#)

BlackBerry® Connect
Med BlackBerry® Connect-programmen får du större möjligheter med vissa Sony Ericsson-telefoner att säkra trådlös åtkomst till e-post, e-postsynkronisering, visning och nerladdning av bilagor med mera.
[Läs mer och ladda ner](#)

Microsoft® Exchange ActiveSync®
Med Microsoft® Exchange ActiveSync® kan du ansluta vissa Sony Ericsson-telefoner till företagets Exchange-server så att du kan hålla e-post, kalender och kontaktinformation uppdaterad på telefonen, var du än är.
[Läs mer och ladda ner](#)

Installationsplats: på datorn

Installationsplats: på telefonen

Installationsplats: på telefonen

3. Install and start the PC Suite.
4. Select "Phone mode" in the mobile phones USB connection settings.
5. Connect the mobile phone to the PC using the included USB cable.

PC Suite for Sony Ericsson

Synkronisera nu

Telefonanslutning

Select "Phone mode" on the telephone!

File Manager Mobile Networking Wizard Backup Manager Download Language

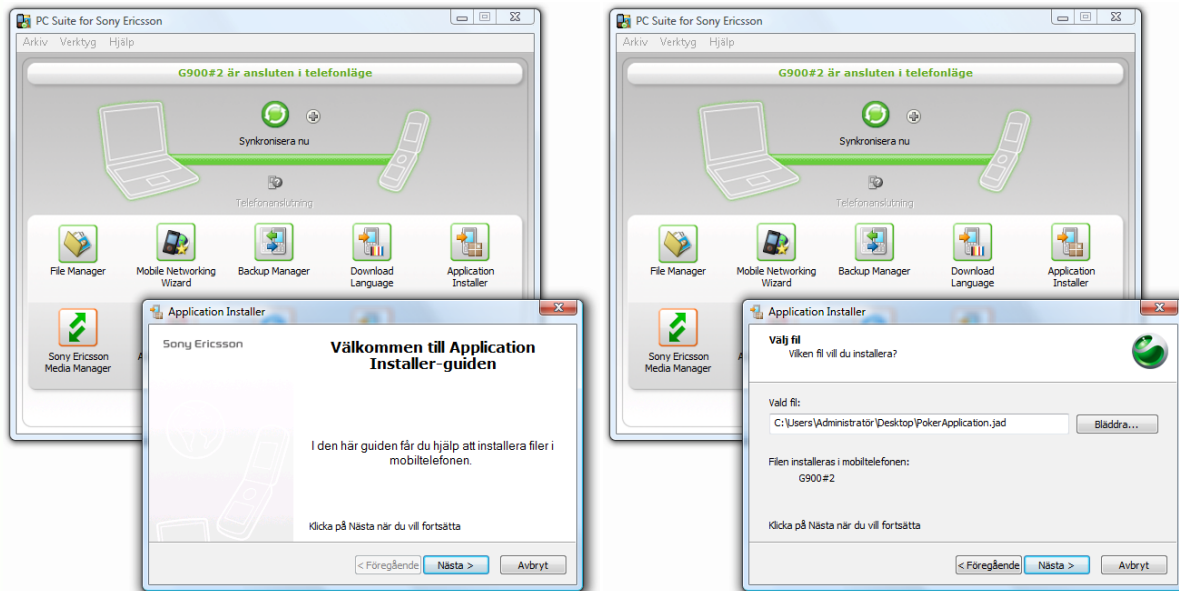

Application Installer

Sony Ericsson Media Manager Adobe Photoshop Album SE Apple QuickTime Player Sony Ericsson Update Service

Sony Ericsson

When you have connected the mobile phone to the PC and selected the option “Phone mode” on the mobile phone, then the PC Suite will show a green communication line between the PC and the mobile phone.

Next, select “Application Installer”. The first time, a file association dialog may appear. When closed, the application installer wizard will open. The following times, the wizard appear immediately.

Select the PokerApplication.jad file and continue to install the MIDlet to your mobile phone. The installation will first be done using the PC Suite, and then it will require that you continue the installation on the mobile phone.

Once everything is completed, you can find AI Poker application in the Games folder of the mobile phone.

Option 2:

The second option is to upload both Java files, PokerApplication.jar and PokerApplication.jad, to a server. Then access the internet through the mobile phone, type in the url to the PokerApplication.jar file and start the download. The download procedure should automatically start the installation of the MIDlet.

For testing purposes, you can download the poker application using the original (random action-based) client from the following address:

- <http://www.lypson.se/PokerApplication.jar>

Playing AI Poker

Starting the AI Poker MIDlet

Mobile Phone prerequisites:

- It is required that the mobile phones that are used to play AI Poker can run Java applications that are compatible with MIDP 2.0 and CLDC 1.1 (any modern phone).
- It is recommended that the mobile phone that is used to play AI Poker has a resolution of 240x320 pixels (most new phones except budget phones).
- It is required that the mobile phone acting as server must have WLAN.
- It is strongly recommended that the mobile phones acting as clients have WLAN.

About the WLAN requirement

Theoretically, a mobile phone could be a server and connect to the internet using the mobile phone network. However, it seems that that is not possible in practice. Mobile phone operators typically assign mobiles IP addresses that are private, preventing access to them from outside their own network. However, tests during the development of AI Poker have shown that even mobile phones connecting using the same mobile phone network cannot access each other, for reasons not further research. Therefore, it seems that the server phone must have WLAN and connect to the net using the WLAN in order for the program to work.

If the clients do not have access to the same local network as the mobile phone, they must connect to the server phone using the public address (typically the IP address) of the phone. The public IP address is typically the address of the LAN router. That means that the gateway of the server phones LAN must forward all communication for the specified port to the server phone. In order to avoid this advanced extra step, and to remove the cost of mobile internet traffic, it is strongly recommended that the client connects to the same network as the server phone using WLAN.

When connecting to the internet using the network in the University of Halmstad, the "local" IP address you receive is a true public IP address, indicated by the local and public IP addresses having the same value, and you should be able to connect to the address using clients from any network.

Recommended mobile phones

The following list contains some models that should work with AI Poker. The program probably works with a lot of other phones that supports WLAN as well, but that is not tested. Some mobile phones with WLAN only support AI Poker as client, not as server (noted with HTC, a Windows Mobile phone).

- Sony Ericsson G705
- Sony Ericsson C905
- Sony Ericsson XPERIA X1
- Sony Ericsson G900
- Sony Ericsson W960
- Nokia N85
- Nokia N79

Playing the AI Poker MIDlet on the computer

As the screen shots below show, it is very much possible to run several instances of the mobile phone emulator from within NetBeans. This makes testing the program much easier. Note, however, that *starting the same program several times from within NetBeans at (almost) the same time may result in errors*. In order to avoid that, wait a little while after starting one instance of the MIDlet before starting the next instance of the MIDlet.

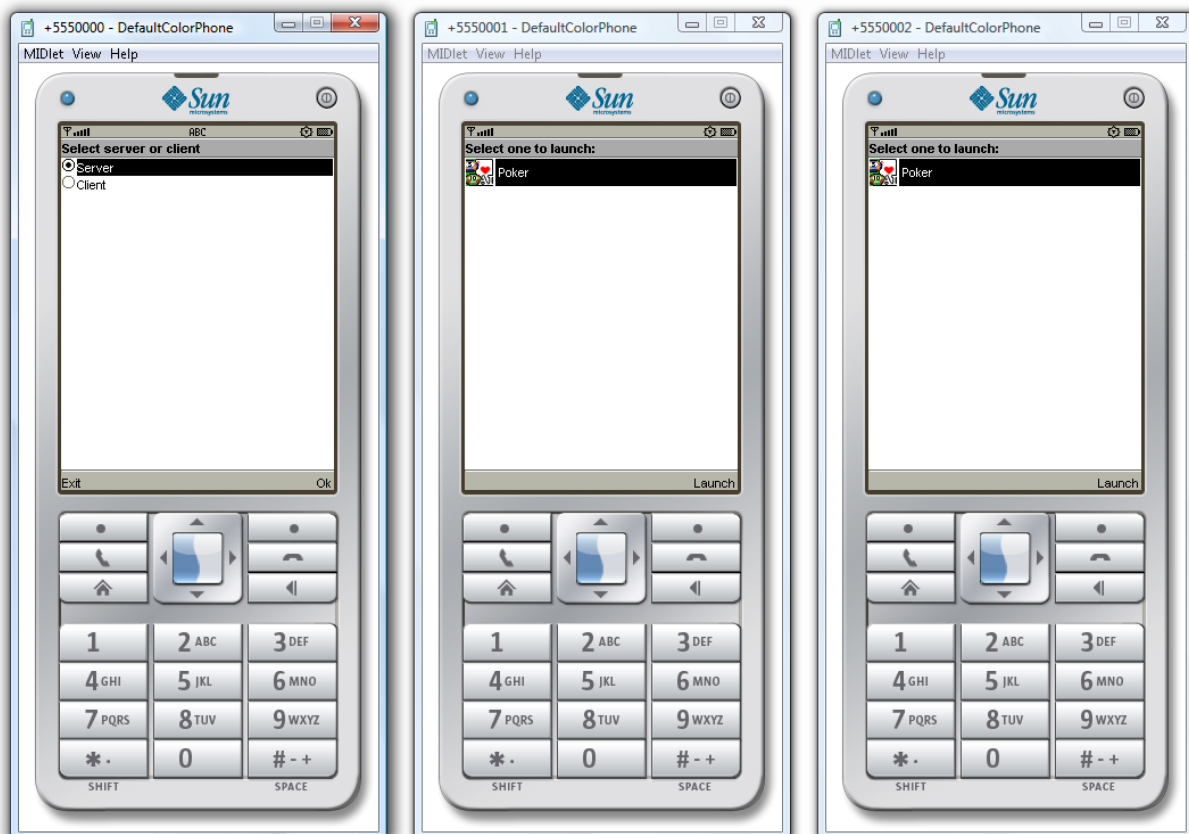

Mix-and-match, clients from both mobile phone and computers

If the mobile phones and the computers all are connected to the same LAN, as recommended, or if the server has a true public IP address, connecting some AI Poker instances running from mobiles with other AI Poker instances running from emulators in computer platforms should not be a problem given that firewalls do not hinder communication.

Running the AI Poker MIDlet

Server or client

When AI Poker is started, you must choose whether you want to run it as a server or as a client.

AI Poker requires that a minimum of three and a maximum of six AI Poker MIDlets run simultaneously: One server and two to five clients⁹. The server controls the whole game while the clients participate in the game, playing against each other.

⁹ Given that we do not want to reinsert discarded cards into the deck again, can you figure out why the maximum number of clients is five?

Server Setup:

When the AI Poker server is started, there are several settings that can be changed by the user:

Server Setup

Server port: 5000

Number of clients: ♠ 2

Players initial amount of chips: 200

Initial ante: 10

Raise ante every # rounds (0 disable): 10

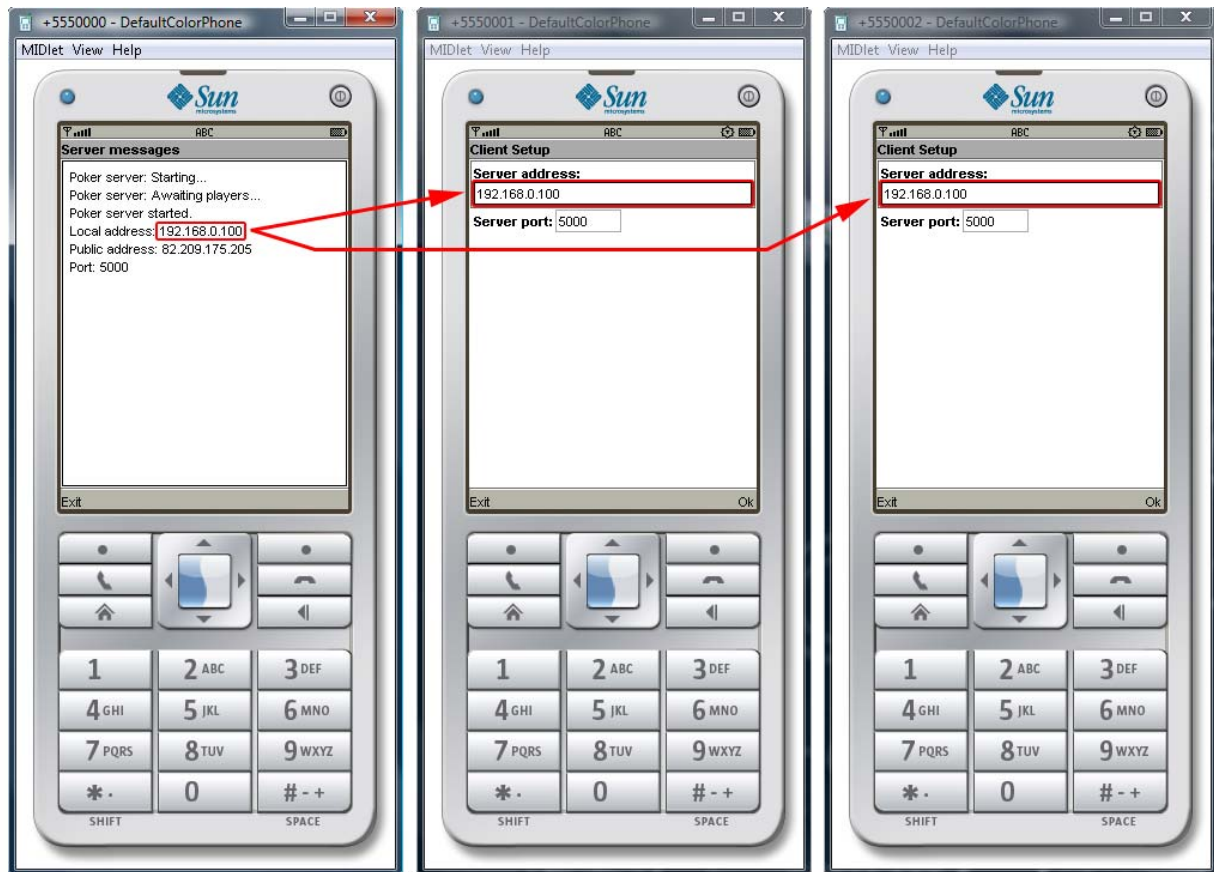

Client response time (ms) 10000

10

1. The server port is set to 5000 as default, but it can be changed to any suitable number.
2. The default number of clients is two, in order to simplify testing.
3. The amount of chips is set to 200 as default for each player and should not be increased (since the graphical images on the server may look odd if the screen should display more than 5x200 in coins).
4. The initial ante is set to 10, but can be changed to any number between 1 and 100.
5. The ante can be doubled for every round that is a multiple of the specified value. If the default values are kept, the ante is 10 for round 1-10, 20 for round 11-20, 40 for round 21-30, 80 for round 31-40, etc.
6. The client response time is set to 10 000 ms, but can be changed to any strictly positive number. If a player does not respond to a query from the server within the specified time, the server disconnects the player.
7. (Option not shown.) The server can play casino music during the game. If you want to listen to good music, or at least any music, while watching the game progress, check this box. By default, this option is not checked.

¹⁰ The screen shot is from the emulator included with NetBeans 6.1 with Mobility Pack. It will look different on a real phone.

In the next step the server application shows its local and public IP-address:

If the server application is run on the PC in an emulator and the Clients are emulators/mobile phones connected to the same networks then the clients can chose to use the Local address.

Tests have shown that starting the server on a real mobile phone like Sony Ericsson G900 will often result in failure. The reason for that is not determined and does not affect the emulators. If the server fails, instead of the IP addresses the message "Poker Server: The socket server has closed" will be displayed. If this occurs, the server must be restarted and you have to try again. Sometimes it helps to change the port number to a different value.

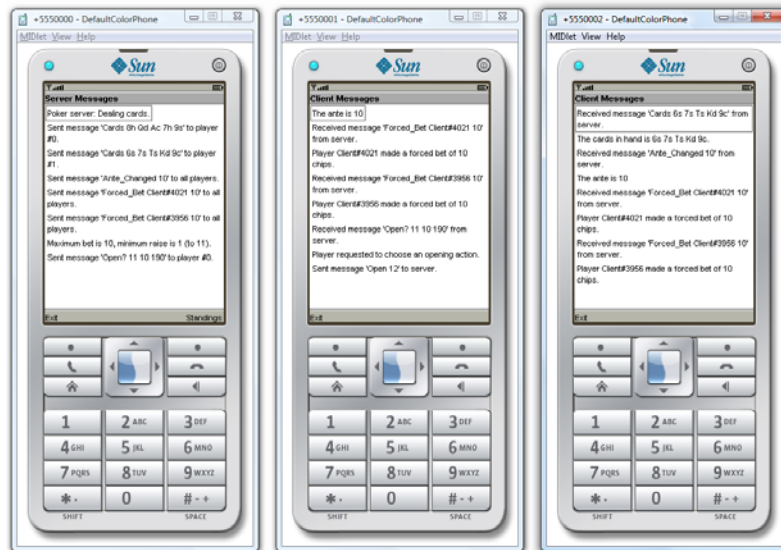

Client Setup:

The server may be either an emulated phone running on a PC or a real mobile phone such as Sony Ericsson G900.

When an AI Poker MIDlet is started as client, there are only two settings that can be changed: The server address and the server port. Both of these are displayed on the servers screen.

- If you are connected to the same LAN as the server, as recommended, you should enter the servers local IP address in the clients setup; otherwise, use the public address.
- It is strictly speaking not necessary to enter an IP address as the server address; if the server has an associated name it can be used instead. If both the server and the client are run on the same computer, the client can use *localhost* as the servers address.

During gameplay

During the game the server and all the clients will display text that contains information about what is happening during the game and what choices the clients are making.¹¹

Tests have shown that Sony Ericsson G900, for reasons unknown, will lag behind in what information is displayed on the clients' screens. This does not seem to affect the emulators, other brands of mobile phones, the game play on the Sony Ericsson phone, or the Sony Ericsson phone when it acts as a server.

You can switch between two views in the server application: Standings and Messages. Messages will display all information in text, just like the clients. Standings will show a graphical image of the game where each players cards and the amount of chips they have are shown. The amount of coins shown on the table is the amount of coins that each client has left to use during the game, not the amount of coins they are currently betting.

¹¹ What is displayed on the clients screen is determined by the client. The default SocketClient class sends all information it receives to the screen, but if you change the class, you can add more or less information to display.

AI Poker rules

Players in AI Poker act in turn, in clockwise rotation.

The game starts by forcing each player to bet an **ante** (a forced bet). Once the bet has been set, each player will receive five cards from the server.

When it is a player's turn to act, the first action he takes binds him to his choice of action and changing his action after seeing how other players react to his initial action is not permitted. Once each player has received five cards the round can start. The first player can then choose to make one of a few specific actions:

- Until the first bet is made each player in turn may **"check"**, which is to not place a bet, or **"open"**, which is to make the first bet.
- After the first bet each player may **"fold"**, which is to drop out of the hand losing any bets they have already made; **"call"**, which is to match the highest bet so far made; or **"raise"**, which is to increase the previous high bet.

Each game, every player will receive a specified amount of chips¹² which they can use for betting. The maximum amount of chips during a game, the amount the winner will have when the game is over, are the sum of all players initial amount of chips.

Six (6) different types of chips exist:

- A "1-coin" chip.
- A "5-coins" chip.
- A "10-coins" chip.
- A "25-coins" chip.
- A "50-coins" chip.
- A "100-coins" chip.

Actions

Each round in the AI Poker game goes through a number of different steps. These steps are as follows:

1. Ante is set and cards are distributed.
2. The first betting round is made.
3. If any players remain in the game, then each player can choose to change cards.
4. The second betting round is made.
5. Showdown, where the players hands are compared and the winner(s) will receive the pot (or part of the pot, in case of multiple winners).

A betting round ends when each none-broke player has either bet an amount equal to the maximum bet, folded or gone all-in. If no opponents call a player's bet or raise, the player wins the pot.

Open

The act of making the first voluntary bet in a betting round is called opening the round. On the first betting round, it is also called opening the pot.

¹² The default amount of chips is 200.

Call

To call is to match a bet or a raise.

Check

If no one has yet opened the betting round, a player may pass or check. When checking, a player declines to make a bet; this indicates that he does not wish to open, but does wish to keep his cards and retain the right to call or raise later in the same round if an opponent opens. If all players check, the betting round is over with no additional money placed in the pot other than the ante (the forced bet) from each player.

Raise

To raise is to increase the size of the bet required to stay in the pot, forcing all subsequent players to at least call the new amount if they want to stay in the round. The act of opening is a special case of raising, done when no other player has raised yet. A player making the second (not counting the open) or subsequent raise of a betting round is said to re-raise. In AI Poker the raise must be at least as high as the previous raise (if any).

If, due to an open or raise action, a bet has been placed that the player in-turn cannot match, then unless that player chooses to go all-in, he must fold. A player must at least match the bet and cannot check or call with a lesser amount.

Fold

To fold is to discard one's hand and forfeit interest in the current pot. No further bets are required by the folding player, but the player cannot win.

Ante

An ante is a forced bet in which each player places an equal amount of money or chips into the pot before the deal begins.

Hands

In AI Poker, players construct hands of five cards according to predetermined rules. These hands are compared using a standard ranking system, and the player(s) with the highest-ranking hand wins that particular deal.

The strength of a hand is increased by having multiple cards of the same rank, all the cards being from the same suit, or having all the cards with consecutive values. The position of the various possible hands is based on the probability of being randomly dealt such a hand from a well-shuffled deck.

The following general rules apply to evaluating poker hands in AI Poker:

- Individual cards are ranked A (high), K, Q, J, 10, 9, 8, 7, 6, 5, 4, 3, 2, A. Aces only appear low when part of an A-2-3-4-5 straight or straight flush.
- Suits have no value. The suits of the cards are mainly used in determining whether a hand fits a certain category (specifically the flush and straight flush hands). If two players have hands that are identical except for suit, then they are tied and split the pot.
- A hand always consists of five cards.
- Hands are ranked by category, and even the lowest qualifying hand in a certain category defeats all hands in all lower categories. The smallest two pair hand, for example, defeats all hands with just one pair or high card.

These are the standard poker hands in descending order:

STRAIGHT FLUSH**FOUR OF A KIND****FULL HOUSE****FLUSH****STRAIGHT****THREE OF A KIND****TWO PAIR****ONE PAIR****HIGH CARDS**

There are 311,875,200 ways ("permutations") of being dealt five cards from a 52-card deck, but since the order of cards does not matter there are 2 598 960 possible distinct hands ("combinations").

There are 40 possible straight flushes (five consecutive cards of the same suit), including the four Royal Flushes (ace to ten in the same suit). The probability of being dealt a straight flush is $40 / 2\,598\,960 = 0.0015\%$.

There are 624 possible hands including four of a kind (four cards of the same value in different suits); the probability of being dealt one is 0.024%.

There are 3,744 possible full houses (three cards of one value, two cards of another value, regardless of suit); the probability of being dealt one in a five-card hand is 0.14%.

There are 5,148 possible flushes (five cards of the same suit), of which 40 are also straight flushes; the probability of being dealt a flush in a five-card hand is 0.20%.

There are 10,240 possible straights (five consecutive cards), of which 40 are also straight flushes; the probability of being dealt a straight in a five-card hand is 0.39%.

There are 54,912 possible three of a kind hands (three cards of the same value) which are not also full houses; the probability of being dealt one in a five-card hand is 2.1%.

There are 123,552 possible two pair hands (two cards of one value, two other cards of another value) that are not also full houses; the probability of being dealt one in a five-card hand is 4.75%.

There are 1,098,240 possible one pair hands (two cards of the same value); the probability of being dealt one in a five-card hand is 42.26%.

Of the 2,598,960 possible hands, 1,302,540 do not contain any pairs and are neither straights nor flushes. As such, the probability of being dealt "high card" in a five-card hand is 50.12%. The value of the hand is the highest individual value of the cards in the hand.

http://en.wikipedia.org/wiki/List_of_poker_hands

Pots and side-pots

Normally, each players bet are put into the main pot and the player with the best hand wins the pot. If several players have hands of the same rank, the pot is split equally between them. A player cannot win more from each of the other players when he himself has bet, so if a player has to few chips to call and goes all-in, a side-pot is created. Each player the all-in amount of chips from the main pot into the side pot (or all money if the player has folded), keeping the remaining amount of chips in the main pot. During the showdown, the best player(s) contributing to the side pot wins the side pot, while the best player(s) contributing to the main pot (this excludes the player that won all-in) wins the main pot. If several players go all-in, several side-pots can be created.

Due to side-pots, it is possible to have several winners in a round even if they have hands of different ranks.
